

Precision 3D scan, Alignment and MCNP Simulation of a 100 μm Neutron Collimator at DICER

--- When modern engineering is applied to a legacy facility

Josef Svoboda, Thanos Stamatopoulos, Dusan Kral, Sotirios Chasapoglou,

Introduction: Motivation

- We are installing 100 μm collimator in Lujan Center, inside FP13 (DICER)
- Legacy facility design introduces many geometric uncertainties—especially impactful for fine spallation target configurations and precise collimation systems.
- A new spallation target design was installed in 2022 and accurate understanding of the as-built facility through 3D scanning has proven essential.
- Our workflow spans from 3D scanning to MCNP modeling—culminating in geometry potential optimization.

DICER instrument

- Neutron beamline at LANSCE designed for indirect capture experiments on radionuclides
- Enables high-precision cross-section measurements using neutron transmission
- Supports low-activity samples and reduced radiation risk through optimized collimation

FP13 100 μm collimator:

Legacy Facility, Modern Demands

FP13 – DICER (Device for Indirect Capture Experiments on Radionuclides)

Short analogy:

Documents \rightarrow digitized \rightarrow searchable
Facilities \rightarrow scanned \rightarrow analyzable

- High-fidelity MCNP requires **accurate starting geometry**
- Legacy documentation \rightarrow **incomplete and unreliable geometry**
- We build a pipeline: **3D scan** \rightarrow **CAD** \rightarrow **MCNP** with a goal: **3D scan** \rightarrow **MCNP**
- Key challenge: turning scan data into simulation-ready geometry

Accurate neutron simulations require accurate geometry—and legacy facilities don't have it. We built a full pipeline from scan \rightarrow CAD \rightarrow MCNP \rightarrow alignment to fix that.

Simulation Challenge & Approach (FP13 – DICER)

Key Challenges

Unknown facility geometry

- Proton beam shape & position
- Target position and FP axis
- Upstream collimator effects

Unknown collimator geometry

- Exact position
- As-built shape

Extreme conditions

- 100 μm aperture at ~ 15 m
- Non-uniform neutron source

Our Approach

- Comprehensive 3D scanning
- Target, shutter ports, flight path, detectors
- LiDAR + Laser Tracker + optical scans
- Precise alignment
- Monument-based Laser Tracker system
- Collimator tightly referenced to beam axis
- Simulation-ready modeling
- As-built geometry \rightarrow CAD \rightarrow MCNP
- Pixelized neutron source for non-uniform emission

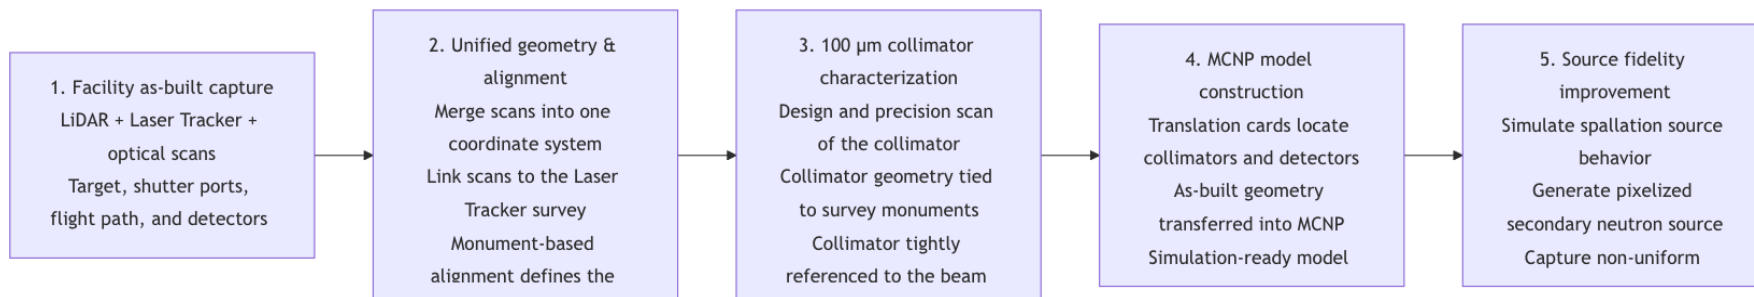

High-fidelity MCNP simulation – legacy facility constrains

Before building a high-fidelity model, we must ask:

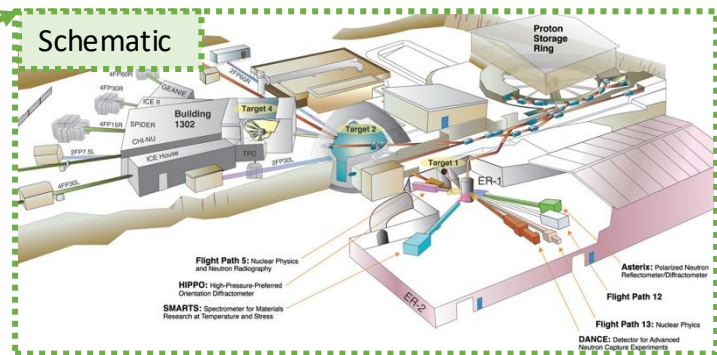

- ❖ What do we *actually* know about geometry?
- ❖ What are the tolerances?
- ❖ Was the *as-designed* geometry validated?
 - LiDAR
 - Laser Tracker Survey
 - Direct Scan (Point Cloud)
 - Spatial Scan (Measured Points of Reflective Sphere)
 - Optical Scan (Structured–light)
 - Profilometer
- ❖ How can we use these data for *as-built* MCNP geometry?
 - Constructive Solid Geometry (CSG)
 - Unstructured Mesh (UM)
 - Hybrid approaches (CSG+UM)

From Legacy Facility to High-Fidelity Simulation

- High-fidelity MCNP requires **accurate starting geometry**
- Legacy documentation → **incomplete and unreliable geometry**
- We build a pipeline: **3D scan** → **CAD** → **MCNP**
- Key challenge: **turning scan data into simulation-ready geometry**

From image to terrestrial LiDAR scan (3D point cloud)

From Image to 3D point cloud

From RAW 3D scan to clean Point Cloud

From As-Built Facility Scans to Flight Path 13 Modeling

Aligned point cloud with Revit CAD structure

Frames: AS BODY FRAME to AS BODY FRAME2

X	0.007	Rx	0.0019
Y	0.005	Ry	-0.0044
Z	-0.115	Rz	-0.0057
d	0.115	TAng	0.0075
Units: (mm)		/	(deg)

All Collimators alignment
to new axis to increase flux

Scan to as-built CAD model

Higher Fidelity \neq Linear Effort

What's easy (already solved):

- CSG (as-designed) models
 - for dose, flux, fmesh, time-emission
- CAD \rightarrow MCNP conversion
 - GEOUNED (CAD \rightarrow CSG)
 - Attila4MC (CAD \rightarrow UM)

What's hard (this work):

- Converting *as-built scans* into MCNP geometry
 - Point cloud as reference \rightarrow adjust CSG geometry
 - Point cloud \rightarrow rebuild CAD \rightarrow convert again
 - Alignment + consistency across datasets

Geometry is no longer idealized—it's measured, noisy, and misaligned

Collimator Alignment: LTS → MCNP

Setup

- Sample collimator (1 mm / 100 μm) with fiducials (SMR nests)
- Laser Tracker defines beam-axis reference
 - Origin: (0, 0, 31.8 cm) {*31.8cm is upper-target level; our target has 2 flight-paths level}

Measurement → Model pipeline

- Spatial Analyzer exports fiducial coordinates
- CAD model aligned using scanned fiducials
- Python workflow converts measurements → MCNP transformation card (TR)
 - Beam blocker
 - Sample collimator
 - Aperture stop
- **Result**
 - Direct mapping of measured positions into MCNP geometry

Outcome

Physically aligned model (not idealized)
Enables first-pass optical / transport simulations with real geometry

MCNP pixelized F1 source

Transporting spallation neutrons over 32 m through a 100 μm sample collimator is extremely challenging.

secondary neutron source

fmesh:F124 @ sample collimator Down Stream

- We are currently looking for faster optical transport – McStas ?
- MCNP is overly robust for these simplified simulations; however, it enables immediate transition to full particle interactions and supports direct comparison across multiple tallies

Manual Source Biasing - Variance Reduction ---

Cutting the secondary neutron source to optimized pixels and cosines

- Pushing neutrons through 100 μm opening @ 15m from spallation source is challenging without f5 tally or DXT, postprocessed pixelized SDEF helps

Proton Beam Position and Shape

- In addition to geometric discrepancies, neutron flux and background levels depend on the proton beam's position and shape
- We post-process each proton bunch using HARP monitor data to adjust the simulations

All beam positions between 2023-11-13 13:20:01+00:00 and 2023-11-13 13:29:59+00:00
angle for XX: 28.31 degrees (x-axis = beam direction)

Summary – DICER - 100 μm collimator

- We redesigned the DICER collimator to minimize sample activity, dose, and measurement cost while maintaining high precision.
- We are developing a full pipeline: **3D scanning** → **alignment** → **CAD** → **MCNP**, enabling accurate *as-built* geometry in simulations.
- We integrate LiDAR, laser tracker, and optical scans to achieve **precise, measurement-based alignment** of all components.
- The spallation target is modeled as a **pixelized neutron source**, capturing spatial non-uniformity and enabling fast simulations.
- Transporting neutrons through a **100 μm collimator over 32 m remains challenging**, requiring precise alignment and modeling.
- Ongoing work focuses on **automation and closed-loop integration** (scan → model → simulation → update).
- First experiment is planned for this run cycle (2026)
- High demand for a new MCNP feature: direct STL geometry import (anticipated in MCNP6.4).

Thank you for your attention.
